Problem:

- Have a set of points $\{x^{(1)}, \dots, x^{(m)}\}$ in \mathbb{R}^n
- Want to lossy compress them using function f, s.t. $f(x) = c \in \mathbb{R}^l$
- Then reconstruct them back using function g, so that $x \approx g(f(x))$. Let g(c) = Dc where $D \in \mathbb{R}^{n \times l}$ have orthogonal columns

It is more often formulated as dimensionality reduction that maximizes variance of the data.

If we have one point, the objective is to minimize the L^2 norm:

$$c^* = \arg\min_{c} ||x - g(c)||_2$$

$$= \arg\min_{c} ||x - g(c)||_2^2$$

$$= \arg\min_{c} (x - g(c))^\top (x - g(c))$$

$$= \arg\min_{c} x^\top x - 2x^\top g(c) + g(c)^\top g(c)$$

$$c^* = \arg\min_{c} -2x^\top g(c) + g(c)^\top g(c)$$

$$= \arg\min_{c} -2x^\top Dc + c^\top D^\top Dc$$

$$= \arg\min_{c} -2x^\top Dc + c^\top c$$

Solve by differentiation:

$$\nabla_c - 2x^{\top}Dc + c^{\top}c = 0$$
$$-2D^{\top}x + 2c = 0$$
$$c = D^{\top}x$$

This makes $f(x) = D^{\top}x$ and $g(f(x)) = DD^{\top}x = x$, a perfect reconstruction.

For all the points X (with stacked $x^{(i)}$), we minimize (where $D^TD = I$):

$$D^* = \arg\min_{D} ||X - XDD^{\top}||_F^2$$

Take the special l = 1 case (first principle component):

$$\begin{split} \boldsymbol{d}^* &= \arg\min_{\boldsymbol{d}} ||\boldsymbol{X} - \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top||_F^2 \\ &= \arg\min_{\boldsymbol{d}} \mathrm{Tr}((\boldsymbol{X} - \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top)^\top (\boldsymbol{X} - \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top)) \\ &= \arg\min_{\boldsymbol{d}} - \mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) - \mathrm{Tr}(\boldsymbol{d} \boldsymbol{d}^\top \boldsymbol{X}^\top \boldsymbol{X}) + \mathrm{Tr}(\boldsymbol{d} \boldsymbol{d}^\top \boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) \\ &= \arg\min_{\boldsymbol{d}} - 2\mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) + \mathrm{Tr}(\boldsymbol{d} \boldsymbol{d}^\top \boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) \\ &= \arg\min_{\boldsymbol{d}} - 2\mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) + \mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top \boldsymbol{d}^\top) \\ &= \arg\min_{\boldsymbol{d}} - 2\mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) + \mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) \\ &= \arg\min_{\boldsymbol{d}} - \mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) \\ &= \arg\max_{\boldsymbol{d}} \mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) \\ &= \arg\max_{\boldsymbol{d}} \mathrm{Tr}(\boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d} \boldsymbol{d}^\top) \\ &= \arg\max_{\boldsymbol{d}} \mathrm{Tr}(\boldsymbol{d}^\top \boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d}) \\ &= \arg\max_{\boldsymbol{d}} \frac{\boldsymbol{d}^\top \boldsymbol{X}^\top \boldsymbol{X} \boldsymbol{d}}{\boldsymbol{d}^\top \boldsymbol{d}} \end{split}$$

This the the form of a Reyleigh quotient. The d that maximizes the expression is the eigenvector of $X^{\top}X$ that corresponds to the largest eigenvalue. Calculating the product $X^{\top}X$ is sometimes not easy. We can instead do SVD on X:

$$X = U\Sigma V^{\top}$$

$$X^{\top}X = V\Sigma^{\top}U^{\top}U\Sigma V^{\top}$$

$$X^{\top}X = V\Sigma^{2}V^{\top}$$

Which means V are the eigenvectors of $X^{\top}X$ and the projections are:

$$XV = U\Sigma V^{\top}V = U\Sigma$$

It is also standard to center data before doing PCA.
